Project Name	Auto Ticket Classification using Flow Designer
Maximum Marks	3 Marks

Proposed Solution

This document presents the proposed solution for automating IT incident ticket classification using ServiceNow's Predictive Intelligence and Flow Designer.

1. Solution Overview

The Auto Ticket Classification system leverages ServiceNow's built-in Predictive Intelligence framework to train machine learning models on historical incident data. When a new incident is created (via Service Portal, email, or Virtual Agent), a Flow Designer flow is triggered that invokes the trained ML model to predict the Category, Subcategory, Priority, and Assignment Group. If the prediction confidence exceeds 80%, the ticket is auto-classified and routed. If below threshold, it is flagged for manual agent review.

2. Key Components

a) Predictive Intelligence (PI) Solution:
- Training Dataset: 12 months of historical incident data (~50,000 records)
- Input Field: Short Description + Description (combined text)
- Output Fields: Category, Subcategory, Assignment Group
- Algorithm: ServiceNow built-in NLP classification (Naive Bayes + Word2Vec)
- Retraining Schedule: Weekly automated retraining

b) Flow Designer Automation:
- Trigger: After Insert on Incident table
- Main Flow: 'Auto Classify Incident'
- Subflow 1: 'Get PI Prediction' - Calls Predictive Intelligence API
- Subflow 2: 'Assign Based on Category' - Maps to assignment group
- Subflow 3: 'Handle Low Confidence' - Routes to manual queue
- Subflow 4: 'Send Notifications' - Notifies agent and end user

c) Agent Workspace Enhancement:
- Confidence score displayed on incident form
- Override button for agent corrections
- Side panel showing prediction rationale

d) Performance Analytics Dashboard:
- Classification accuracy trend
- Auto vs. manual classification ratio

- Top misclassified categories
- MTTR comparison (before vs. after automation)

3. Expected Benefits

- 80% reduction in manual classification effort
- Misrouting rate reduced from 22% to < 5%
- Average classification time: < 3 seconds (vs. 3-5 minutes manual)
- 30% improvement in SLA compliance
- Consistent classification quality 24/7
